### Abstract

Internet addiction poses a significant concern for adolescents, particularly those diagnosed with Asperger's syndrome. Although empirical research focusing on adolescents with Asperger's syndrome is limited, existing findings reveal several neurocognitive and mental health factors contributing to internet addiction. Impulsivity, attention deficits, social skills deficits, cognitive rigidity, and co-occurring anxiety and depression are among the key aspects identified. Understanding these factors is essential for developing effective interventions. This review discusses neurocognitive and mental health aspects of internet addiction in adolescents with Asperger's syndrome as well as potential interventions targeting these aspects to promote healthy internet use and overall well-being in this unique population.

### Keywords

internet addiction, Asperger's syndrome, adolescents, neuropsychological aspects, interventions

### Introduction

Internet addiction has emerged as a significant concern among adolescents, with particular relevance to those diagnosed with Asperger's syndrome [1]. Autism spectrum disorder (ASD) is a neurodevelopmental condition that is marked by difficulties in social communication, as well as the presence of limited interests and repetitive behaviors. In particular, individuals with ASD often engage ineffectively in social interactions and may exhibit a narrower range of interests and activities [2]. This review aims to discuss the neuropsychological aspects related to internet addiction in this population and shed light on targeting interventions.

The review on the neurocognitive characteristics of individuals with Asperger's syndrome and interventions for their internet addiction holds paramount importance for various reasons. Firstly, understanding the unique neurocognitive features associated with Asperger's and their potential relationship with internet addiction can provide crucial insights into the underlying mechanisms of this condition. Such insights may aid in identifying specific vulnerabilities in this population, leading to the development of tailored interventions aimed at improving their overall

well-being and quality of life. Additionally, by addressing gaps in the existing literature, this review can pave the way for future cross-disciplinary studies, longitudinal research, and increased diversity in samples, fostering a more comprehensive understanding of the subject and contributing to the advancement of both Asperger's syndrome and internet addiction studies. By gaining a comprehensive understanding of the unique neurocognitive features associated with Asperger's and their potential link to internet addiction, clinicians can design interventions that are specifically tailored to address the individual needs and challenges of this population.

Acknowledging the complexity of internet addiction and the specific needs of adolescents with Asperger's, it is crucial to tailor treatment plans accordingly [3]. Collaborating with professionals specializing in both internet addiction and ASD can provide invaluable guidance and support throughout the treatment process. Internet addiction poses a significant concern for adolescents, particularly those with Asperger's syndrome. To effectively address this issue, a comprehensive understanding of the neuropsychological aspects of internet addiction and the implementation of appropriate interventions

are crucial. Despite limited research focused on this population, established strategies and approaches can be utilized to develop targeted interventions. These interventions incorporate psychoeducational components, clear guidelines and boundaries for internet use, and cognitive-behavioral therapy techniques to address maladaptive thoughts and behaviors related to internet use.

Moreover, individualized interventions that consider the unique challenges faced by adolescents with Asperger's are essential. This may involve integrating social skills training programs to target difficulties in offline social interactions and promote healthy peer relationships. Parental involvement and support play a crucial role in facilitating behavior change, and interventions should empower parents with education and tools for effective monitoring and regulation of their ado's internet use [4,5].

This approach should encompass a comprehensive understanding of the specific neuropsychological factors associated with internet addiction within this unique population. The issue of internet addiction carries significant implications for adolescents, particularly those with Asperger's syndrome. Namely, they may face compounded negative effects from excessive electronics use, given their pre-existing difficulties in social and academic domains [6]. Problematic electronics use can limit opportunities for developing important skills, resulting in additional strain on families who are already under significant stress [7], although electronics can have beneficial applications for individuals with ASD, such as aiding in teaching and communication [8]. Therefore, it is of utmost importance to cultivate a comprehensive understanding of the intricate neuropsychological aspects of internet addiction and implement appropriate interventions specifically designed for this population. Although empirical research specifically targeting internet addiction in adolescents with Asperger's syndrome remains limited, certain general strategies and approaches hold promise.

## Methods

The present study is a narrative review that explores the neuropsychological aspects of internet addiction among adolescents with Asperger's syndrome and examines the effectiveness of interventions in this population. The review follows a comprehensive approach to synthesize and analyze existing literature related to psychoeducation and internet addiction therapy for adolescents with Asperger's syndrome.

A systematic search of academic sources was conducted using reputable databases, including PubMed, PsycINFO, Scopus and Google Scholar. Relevant keywords and combinations, such as "Asperger's syndrome," "neuropsychological aspects," "internet addiction," "adolescents," "psychoeducation," "interventions," "neurocognitive deficits," "executive functioning," "social cognition," "self-regulation," "impulse control," "psychoeducation," "internet addiction therapy," "parents," was employed.

The inclusion criteria were carefully designed to focus on studies that explicitly addressed the neuropsychological aspects of Asperger's syndrome in relation to internet addiction in adolescents. Articles eligible for inclusion needed to discuss psychoeducation interventions and internet addiction therapy targeted at adolescents with Asperger's syndrome.

Articles were meticulously screened based on their titles

and abstracts to identify those that specifically delved into the neurocognitive aspects of Asperger's syndrome in relation to internet addiction and the effectiveness of psychoeducation interventions for both adolescents and their parents. The selected articles were then subjected to a rigorous evaluation to extract crucial insights into the efficacy of these interventions in addressing the unique neuropsychological challenges experienced by adolescents with Asperger's syndrome.

Throughout the narrative review, considerable effort was made to integrate relevant research on psychoeducation interventions for both adolescents with Asperger's syndrome and their parents, with a specific emphasis on the neurocognitive aspects related to internet addiction in this population. By prioritizing this tailored approach, this narrative review aimed to provide a comprehensive and insightful overview of the current state of knowledge regarding interventions for internet addiction in adolescents with Asperger's syndrome, emphasizing the importance of addressing their specific neuropsychological needs. The findings from this review contribute to a better understanding of the complexities of internet addiction in adolescents with Asperger's syndrome and highlight the significance of addressing their unique neuropsychological challenges in developing effective interventions.

## Results

The data analysis was performed using IBM SPSS V23. Shapiro-Wilk test was used in testing if the data fit the normal distribution. Mann-Whitney U test was utilized in comparing the data that did not fit the normal distribution in paired-group comparisons. In the comparisons between three or more groups, the Kruskal-Wallis test was used for data that did not follow a normal distribution and multiple comparisons were performed using the Dunn test. Yates correction, Fisher's Exact test, and Pearson chi-square test were utilized for the comparison of categorical variables according to groups and multiple comparisons were made using the Bonferroni correction. The analysis results are expressed in frequency (percentage) for categorical variables and mean  $\pm$  SD and median (minimum-maximum) for quantitative variables. The significance level was set at  $p < 0.050$ .

## Neurocognitive characteristics

### Problems in the frontal lobe

Due to dysfunction of the frontal lobe as well as executive functions, individuals with ASD show deficits in theory of mind [13], which is reflected in their social interactions and specifically in the inability to recognize and perceive the mental states of others, but expression of their own internal state [14]. The application of social norms of behavior in each context is also affected by these deficits [15]. Theory of Mind (ToM) refers to the individual's ability to describe mental states (perceptions, goals, desires) and to understand that others may have a different opinion and intention, while its development is essential as it contributes in self-organization, self-regulation, and managing the behaviors of others and is a resource at school, at home, and at work [16].

According to the ToM, in people with autism certain abilities related to sociability, communication, empathy, and creative imagination seem insufficient, as these people have difficulty perceiving ideas, feelings, and mental states, while the development of imagination and symbolic operation are limited. Inadequate mental representations and rigid behavior,

difficulty developing speech, indifference to the expression of others, difficulty maintaining a conversation and problems in verbal and non-verbal communication, in turn, hinder mutual communication and interaction, while simultaneously making it difficult to achieve future goals [13]. This deficit is also referred to as mental blindness emphasizing the difficulty of these individuals to separate the world of the mind from that of reality [17]. This, in some cases, leads to the emergence of certain compensatory skills, such as ingenuity and innovation. Also, people with ASD cannot describe the world using their social and human interactions, feelings, and reactions and struggle in areas such as imagination, metaphors, and critical thinking. In this way, they are led to further isolation and limited opportunities to engage in group activities and play contexts. Children's cognitive development is linked to their developing executive skills.

Deficits in the frontal lobe, according to the executive cognitive dysfunction approach, result in executive cognitive dysfunctions giving individuals with ASD characteristics such as deficits in cognitive flexibility, self-control, sustained action and attention, memory, and planning and organizing abilities, and engaging in specific interests and strategies in an obsessive and stereotyped manner [18]. These deficits result in behavioral clinical features such as rigid behavior, angry outbursts, obsession with similarity, inappropriate response in social situations, and rigid adherence to specific rituals and routines [19].

Remarkable, moreover, is the difficulty of most individuals with ASD to cope with the slightest changes in the environment, their insistence on following their routine precisely [20], and their compulsive attention to a particular object or activity [21]. In addition, they show no trace of orientation to a future goal and have self-control issues [20].

Additionally, according to the Enhanced Perceptual Capacity theory, individuals with ASD, unlike typically developing individuals, have increased access to low-level perceptual processes. This fact stems from the over-functioning of brain areas responsible for basic perceptual processes or from the under-functioning of mechanisms responsible for high-level cognitive processes [22]. Important is the compensatory function of a cognitive deficit, which can result in the emergence of interests thanks to the practice and overlearning of specific skills [22].

Finally, medial prefrontal lobe dysfunction in individuals with ASD contributes to deficits in the development of empathy and systematization [17]. This has an impact on social interaction, since empathy is cognitively related to theory of mind and one's ability to recognize the emotional and mental state of others and react to observed experiences, while affectively is related to the ability to respond appropriately to emotional state of his fellow men [23]. It is argued that empathy plays a critical role in selfless and positive social behavior, while its lack leads to antisocial behavior [24]. This happens since it serves interpersonal relationships, cooperation and team cohesion [25]. In fact, in some cases incidents of overreaction and underreaction, anger outbursts, self-injurious behaviors, and aggression are likely to occur [21,26,27].

Systematization, on the other hand, refers to the ability of the human brain to investigate and examine the parts of a system, the relationships between them and the rules of its structure [13] and thus be able to predict the behavior of the system. The person with autism is deficient in understanding the sequence of events or the relationship of cause and effect and, for this reason,

tries to impose regularity through a rigid ordering of the world.

According to Baron-Cohen [28], people with ASD show particular potential when dealing with closed systems, with limited diversity, structure, and high regularity (mathematics, calendar calculations, computers), while they have difficulty in open systems with increased diversity (social relationships). In fact, in these individuals these two psychological processes of empathy and systematization have a functional relationship between them.

Systematization is manifested through focusing attention on individual elements of a stimulus, persistent interest and islands of ability [23], satisfactory performance in mathematical calculations and visualization of space, while a task is first treated as a system and then researched repeating patterns that make it up.

Deficits in executive functions are consistently observed throughout childhood and, in fact, do not appear to be related to IQ or verbal ability in individuals with ASD [29]. They lead to a need for uniformity, repetitive behaviors, difficulty controlling impulses, non-routine activities, organizing and planning actions, response inhibition [25]. Response inhibition in typically developing individuals promotes self-control and working memory capabilities, since it concerns their ability to remove task-irrelevant stimuli and focus on important information [25].

Dysfunction of the cognitive processes of mental flexibility and planning, which include mechanisms such as maintaining attention, evaluating and informing, leads to obsessive, stereotyped behaviors, difficulty controlling and changing thoughts and actions, difficulty imitating, movement copying and emotion recognition, as well as focusing or refocusing attention [25]. It refers to the readiness with which the perceptual system adapts accordingly to environmental stimuli [30] and is a key characteristic of creative thinking [31].

Of course, factors that affect performance in similar projects are the general cognitive and verbal functionality of the individual along with the requirements. These deficits result in persistent, stereotyped behaviors with difficulties in switching thought or action, in response to a changing situation and in maintaining stability [25]. Stereotyped behaviors, however, lead to fewer opportunities for social interaction, isolation and loneliness. People with autism get upset with any change and are driven to tensions and inappropriate behavior. Thus, qualitative weaknesses in social interaction are presented, such as the inability to manifest non-verbal behaviors (eye contact, body posture, gestures, facial expressions), the refusal to seek relationships with peers, the absence of social reciprocity and the difficulty of starting and maintaining a conversation.

### **Executive functioning difficulties**

ASD is often associated with executive function deficits, linked to the frontal lobe's functioning [20,32]. They refer to impairments that affect various cognitive abilities, such as planning, adapting to new situations, staying focused on tasks, remembering and manipulating information, and regulating actions and inhibitions [33]. Both children and adults diagnosed with autism have demonstrated difficulties in performing tasks related to executive functions, including impulse control, time management, and self-regulation [34]. These challenges can make it harder for individuals with ASD to moderate their technology use and set healthy boundaries, increasing the risk of developing technology addiction [35].

Adolescents with Asperger's and internet addiction often exhibit impulsive behaviors, such as engaging in online activities without considering the potential consequences [36]. This impulsive tendency may be linked to deficits in inhibitory control commonly observed in this population. Weaker executive functioning, which is often seen in individuals with ASD, can contribute to difficulties in recognizing persuasive design and perceiving the passage of time. These challenges place individuals with ASD at a higher risk for technology addiction or overuse of digital media.

### Attention Deficits

Attention deficits are prevalent in adolescents with Asperger's and may contribute to their susceptibility to internet addiction [37]. Challenges in sustaining attention on tasks and responsibilities can lead to a heightened reliance on the internet as a means of escape or avoidance. The dynamic and engaging nature of online environments may offer temporary relief from difficulties in maintaining sustained focus. Besides, research revealed a correlation between the presence symptoms of attention-deficit hyperactivity and the severity of Internet Gaming Disorder (IGD) in individuals with autistic traits who play video games [9,38,39].

### Social Skills Deficits

Adolescents with Asperger's commonly struggle with social skills, which can result in social isolation and increased dependence on the internet for social interaction [40]. Difficulties in interpreting social cues and understanding social norms may further exacerbate challenges in offline social interactions, reinforcing reliance on the online realm [41]. Individuals with ASD may face challenges in social interactions and forming connections with others. The online world offers a sense of anonymity and reduced social demands compared to face-to-face interactions, making it a more comfortable and accessible environment for individuals with ASD. The internet can serve as a refuge where they can interact with others, find like-minded communities, and engage in activities without the same social pressures encountered offline.

The social challenges experienced by individuals with ASD can also contribute to the co-occurrence of technology addiction. Many individuals with ASD prefer solitary play and leisure time due to difficulties in regulating their nervous system and past experiences of peer rejection. The virtual world, including video games, provides a refuge for individuals with ASD as it offers clear rules, logical thinking, and visual skills that align with their strengths. This attraction to the online realm can lead to excessive screen time and sedentary behavior among individuals with ASD, further exacerbating the risk of technology addiction.

In college settings, autistic students face additional challenges as they navigate the transition without the same support systems they had during their earlier education. Many autistic students struggle with the social demands and self-advocacy required in college, leading them to retreat into online activities such as gaming [40]. Excessive internet use can negatively impact their academic performance and sleep patterns, further complicating their college experience.

To mitigate these challenges, it is crucial for parents and educators to prepare autistic students for the transition to adulthood, including developing necessary skills and finding post-secondary institutions with appropriate supports. Increased awareness and support within universities can also help address the issues faced by autistic students in relation to technology addiction and academic success.

### Cognitive Rigidity

Cognitive rigidity, characterized by a preference for routines and resistance to change, is frequently observed in adolescents with Asperger's [42]. This rigidity may manifest as a compulsion to engage in specific online activities or adhere to rigid internet usage patterns. The structured and predictable nature of online environments can provide a sense of comfort and familiarity, alleviating distress associated with uncertainty or change. The restricted and repetitive patterns of behavior and interests commonly observed in individuals with ASD make the internet alluring. Autistic individuals often develop intense interests in specific topics and can easily find endless content related to their passions online. Through persuasive design, platforms continuously serve targeted content to maintain users' engagement, making it challenging for individuals with ASD to resist the allure.

**Escapism as a Coping Mechanism:** As adolescents with ASD are highly stressed [43,44], they often use many different dysfunctional coping strategies. In general, coping with stress is multifaceted [45,46] and emotion-focused strategies, such as denial is often considered a way to escape from problems and related traumatic experiences [47,48]. Technology, particularly immersive digital media like video games, can provide an escape from real-life challenges and stressors [49]. For individuals with ASD who may struggle with anxiety, sensory overload, or difficulties in navigating the social world [50], engaging in technology-related activities can serve as a coping mechanism and a way to find comfort and predictability.

**Anxiety and Depression:** A significant number of young individuals diagnosed with ASD also fulfill the requirements for an additional psychological condition, such as anxiety or depressive disorders, or display noticeable psychiatric symptoms like feelings of sadness [51]. Several studies [52], [53], [54] have highlighted this correlation between ASD and co-occurring mental health issues or elevated psychiatric symptoms. Thus, co-occurring anxiety and depression, which are commonly observed in adolescents with Asperger's [55] and may contribute to their vulnerability to internet addiction. Symptoms such as excessive worry or social anxiety may drive individuals to seek solace or distraction online. Similarly, feelings of sadness or loneliness can lead to the use of the internet as a means of escape or as a source of virtual companionship.

**Sensory Challenges:** Individuals with ASD often encounter sensory sensitivities, either being overly sensitive or unresponsive to various stimuli [56]. This can prompt them to engage in activities that offer sensory stimulation and regulation. Sensation seeking is a prevalent trait among individuals with ASD, as they may exhibit hyper- or hypo-reactivity to sensory input. This implies that they can be highly sensitive or unresponsive to stimuli such as light, sound, touch, texture, or smell. Consequently, these sensory challenges can become overwhelming, leading individuals with ASD to seek strategies for regulating their nervous system. In certain instances, their behaviors may be misunderstood as disobedience when, in fact, they are attempts to cope with sensory overload. Technology, such as video games, offers a controlled and predictable sensory environment that can be appealing to individuals with ASD. To compensate for sensory difficulties, individuals with ASD may engage in sensory-seeking behaviors to seek positive sensations. Video games and digital media, designed with persuasive techniques, exploit these sensory-seeking tendencies through rewarding cues, animations, and variable reward schedules.

that are highly addictive. This makes individuals with ASD, particularly sensation seekers, more susceptible to the allure of persuasive design.

**Special Interests:** People with ASD often develop intense interests in specific topics. The internet provides a vast array of information and content on these interests, making it easy for individuals with ASD to immerse themselves in online activities related to their special interests. This intense focus and engagement can contribute to excessive internet use and a potential for addiction.

## Interventions

### Cognitive-Behavioral Approaches

Cognitive-behavioral approaches are widely recognized and supported by empirical evidence as highly effective treatments for anxiety, setting the benchmark for psychosocial interventions [57]. Through research, the effectiveness of adapting cognitive-behavioral techniques has been demonstrated [57,58]. The main target is to cater to the unique requirements of individuals with autism, ensuring their needs are met adequately [59].

### Behavioral Therapy

Manualized behavioral therapy interventions have shown promise in benefiting individuals with ASD and substance use disorders [60]. Although these studies primarily target substance use, the principles of behavioral therapy can be extrapolated to address internet addiction as well. Behavioral therapy can facilitate the development of coping skills, trigger management, and modification of maladaptive behaviors.

### Exercise-Based Interventions

Empirical evidence suggests that exercise interventions hold potential for reducing internet addiction [61]. Engaging in physical activities serves as a means to redirect attention away from the internet and provides a healthy outlet for excessive energy. Collaboration with healthcare professionals is advised to determine appropriate exercise options tailored to the unique needs of the adolescent.

### Addressing Co-occurring Conditions

As mentioned above, Asperger's syndrome frequently co-occurs with other mental health conditions such as anxiety or depression [62]. Hence, it is essential to address these underlying conditions, as they may contribute to the development or maintenance of internet addiction. Adopting a comprehensive treatment approach that targets both internet addiction and co-occurring mental health conditions is recommended for optimal outcomes.

### Psychoeducation

Psychoeducation is a well-established approach in mental health, known for effectively addressing various issues [63]. In this context, we explore its potential as an intervention for internet addiction, delving into its applicability and efficacy to foster healthier online behaviors. Psychoeducation is a crucial component in the comprehensive management of internet addiction among adolescents with Asperger's [64]. It involves providing information and education to both parents and adolescents about the nature of internet addiction, its potential consequences, and strategies for prevention and intervention [66]. It endeavors to provide a comprehensive approach by delivering educational sessions that impart knowledge about a specific clinical condition, structured and guided problem-

solving exercises, and opportunities for individuals to receive social support [66]. The primary goal is to alleviate distress experienced within the household and, thereby, improve overall outcomes for all family members involved [67].

### Psychoeducation for Parents

Parents play a pivotal role in supporting adolescents with Asperger's and internet addiction [62]. Establishing open lines of communication, setting appropriate boundaries, and offering guidance can foster a supportive environment. Involving parents in therapy sessions can enhance treatment effectiveness by incorporating their input and perspectives.

The role of parental support is very important, although complicated [67]. Providing parents with a solid understanding of internet addiction is vital for effective support. Psychoeducation empowers parents by equipping them with knowledge about the risk factors, warning signs, and the impact of excessive internet use on adolescent development. Additionally, parents gain insights into the specific challenges faced by adolescents with Asperger's and the unique interplay between their neurodevelopmental profile and internet addiction. Psychoeducational interventions can be delivered through various formats, including individual or group sessions, workshops, or online resources. These interventions offer a platform for parents to acquire practical strategies, parenting skills, and techniques to promote healthy internet use within the family context [68].

### Psychoeducation for Adolescents

Equally important is providing psychoeducation directly to adolescents with Asperger's who are struggling with internet addiction. Adolescents need to understand the potential risks associated with excessive internet use, including compromised social relationships, decreased academic performance, and negative impacts on mental health [69]. Psychoeducation helps adolescents gain awareness of their own internet use patterns, recognize the signs of addiction, and develop insight into the underlying emotional and cognitive processes that contribute to their addictive behaviors. It also provides them with coping strategies, stress management techniques, and alternative activities to cultivate a healthier balance between online and offline activities.

When both parents and adolescents receive psychoeducation, it establishes a common understanding and language around internet addiction, allowing for more effective collaboration and support [70]. It empowers parents to engage in constructive discussions with their adolescents, set appropriate boundaries, and provide guidance based on a shared knowledge base [71]. Furthermore, psychoeducation fosters a sense of agency and self-efficacy in adolescents, enabling them to take ownership of their internet use and make informed decisions about their online behaviors.

The delivery of psychoeducation can be conducted through various mediums, including individual counseling sessions, group therapy, or psychoeducational workshops. It is essential to tailor the information and interventions to the unique needs and characteristics of adolescents with Asperger's. The use of visual aids, social stories, and concrete examples can enhance comprehension and engagement [72]. In addition, online platforms and resources can be leveraged to provide ongoing support and reinforce the concepts discussed during psychoeducation sessions [73].

Integrating psychoeducation into the overall treatment

approach for internet addiction in adolescents with Asperger's enriches the intervention framework by empowering both parents and adolescents with knowledge, skills, and strategies to effectively manage and prevent internet addiction [74]. By promoting shared understanding and collaborative efforts, psychoeducation contributes to the overall success of treatment outcomes and long-term recovery.

## Discussion

To address internet addiction in adolescents with Asperger's, a multifaceted approach is warranted. Interventions should consider the specific neuropsychological aspects associated with internet addiction in this population. Strategies such as cognitive-behavioral therapy, mindfulness-based interventions, parental involvement, and addressing co-occurring mental health conditions are recommended [75,76]. Individualized treatment plans tailored to the unique needs and circumstances of each adolescent should be developed in collaboration with licensed professionals experienced in working with both internet addiction and Asperger's syndrome.

Besides, it is essential to consider the neurocognitive deficits commonly associated with this population and develop targeted interventions. Adolescents with Asperger's syndrome may exhibit difficulties in executive functioning, social cognition, self-regulation, and impulse control, which can contribute to their susceptibility to internet addiction. Interventions targeting executive functioning deficits can be beneficial [77,78]. Cognitive remediation programs that focus on improving cognitive flexibility, working memory, and planning abilities have shown promise in addressing executive function difficulties [79]. Besides, programs should promote resilience, which is a vital skill for individuals coping with traumatic experiences, helping them manage stress, seek support, and foster a growth-oriented mindset [80]. Interventions aimed at promoting resilience should focus on building coping strategies, encouraging social support networks, and fostering a positive outlook on challenges as opportunities for growth. These programs utilize structured exercises and strategies to enhance cognitive skills, which can help individuals with Asperger's syndrome regulate their internet use.

Social skills training interventions can address the social cognition deficits often seen in individuals with Asperger's syndrome [81]. These interventions focus on enhancing social understanding, perspective-taking, and communication skills, which can improve offline social interactions and reduce excessive reliance on online interactions through the internet. By promoting healthier social interactions, individuals with Asperger's syndrome may be less inclined to use the internet as a substitute for face-to-face social connections.

Targeting self-regulation and impulse control is also crucial in addressing internet addiction [82]. Besides, interventions that have been proven to promote self-control, incorporate self-management and exercise-based programs [83-85]. They aim to empower individuals to take charge of their behavior, emotions, and thoughts, while benefiting from regular physical activity to enhance impulse control and emotional regulation. Additionally, interventions such as mindfulness-based approaches, which emphasize awareness of thoughts, emotions, and urges without judgment, can enhance self-regulation skills. Mindfulness training can help individuals with Asperger's syndrome develop the capacity to recognize and manage cravings and impulsive behaviors associated with internet addiction [86].

Furthermore, parental involvement and support play a vital role in interventions for adolescents with Asperger's syndrome and internet addiction [87]. Parents can provide structure, set limits, and monitor internet use, while also fostering open communication and understanding [88]. Collaborative efforts between parents, therapists, and educators can help develop strategies that address specific challenges faced by adolescents with Asperger's syndrome, ensuring a comprehensive and tailored approach [89].

It is important to note that research on specific neurocognitive interventions targeting internet addiction in adolescents with Asperger's syndrome is limited. Further investigation and the development of evidence-based interventions that directly address the neurocognitive deficits associated with both Asperger's syndrome and internet addiction are needed to provide more targeted and effective treatment options. Understanding the neuropsychological aspects specific to this population is crucial for effective intervention. By targeting impulsivity, attention deficits, social skills deficits, cognitive rigidity, and co-occurring anxiety and depression, tailored interventions can be developed to address internet addiction in adolescents with Asperger's. Future research should further explore the underlying mechanisms and effectiveness of interventions in this population.

## Limitations

As with any literature review, certain limitations should be acknowledged. Despite conducting a comprehensive search, it is possible that some relevant studies might have been missed. Additionally, narrative reviews come with inherent constraints concerning impartiality, the thoroughness of literature exploration, and the interpretation of results.

## Conclusion

The literature review aimed to provide a comprehensive overview of the current state of knowledge regarding neurocognitive mechanisms and interventions in adolescents with Asperger's and internet addiction. The findings of this review will help inform further research, identify gaps in the existing literature, and contribute to the development of targeted interventions for this population. In addressing internet addiction in adolescents with Asperger's, the integration and adaptation of evidence-based interventions employed for general internet addiction is crucial. Despite limited research specifically focused on this population, incorporating psychoeducation, clear guidelines, cognitive-behavioral therapy techniques, social skills training, parental involvement, and promoting alternative activities can effectively address internet addiction in this group. Collaboration with mental health professionals experienced in both internet addiction and Asperger's syndrome is vital for developing tailored and evidence-based interventions. By considering the unique needs of adolescents with Asperger's, we can strive to effectively support them in managing their internet use and fostering healthier habits.
